Computed Tomography and Radon Transform

Mathematically, a CT scanner samples the **Radon transform**

$$R(u)(\omega,s) = \int_{-\infty}^{\infty} u(s\omega^{\perp} + t\omega) \,\mathrm{d}t$$

where $s \in \mathbb{R}$ and $\omega, \omega^{\perp} \in S^1$.

The normal operator R^*R is an elliptic Ψ DO of order -1 and a convolutional operator associated with the Calderón-Zygmund kernel:

$$K(x,y) = \frac{1}{|x-y|}$$
 for $x \neq y$.

 $\Gamma = 30^{\circ}$, filtered backprojection (FBP)

Observations:

 R_Γ is a convolutional operator associated with the kernel:

$$K(x,y) = \frac{1}{|x-y|} \chi_{\Gamma}(x-y)$$

for $x \neq y$ and χ_{Γ} indicator function of the visible wedge $[-\Gamma, \Gamma]$.

- R^{*}_ΓR_Γ belongs to the wider class of FIOs, which includes operators associated with a kernel showing discontinuities along lines.
- highly ill-posed inverse problem!

Inverse Problem and Sparsity

Linear inverse problem:

given
$$m = R_{\Gamma} u^{\dagger} + \epsilon \in Y$$
, find $u^{\dagger} \in X$

with $\|\epsilon\|_Y \leq \delta$ (noise), $X = L^2(\Omega)$, $\Omega \subset \mathbb{R}^2$, and $Y = L^2([-\Gamma, \Gamma] \times [-S, S])$.

imited Angle Tomography	IP and Sparsity	ISTA as CNN	⊈D0Net	Results	Conclusions

Inverse Problem and Sparsity

Linear inverse problem:

given
$$m = R_{\Gamma} u^{\dagger} + \epsilon \in Y$$
, find $u^{\dagger} \in X$

with $\|\epsilon\|_Y \leq \delta$ (noise), $X = L^2(\Omega)$, $\Omega \subset \mathbb{R}^2$, and $Y = L^2([-\Gamma, \Gamma] \times [-S, S])$.

The resulting ill-posed inverse problem is usually solved using analytic methods, iterative reconstruction, or sparse regularization. For example:

$$\underset{w \in \ell_1(\mathbb{N})}{\operatorname{argmin}} \left\{ \| R_{\Gamma} W^* w - m \|_Y^2 + \lambda \| w \|_{\ell_1} \right\} \quad \text{ with } \quad w = W u$$

where $W: X \to \ell_2(\mathbb{N})$ is the operator associating to any $u \in X$ the sequence of its wavelets coefficients $(Wu)_I = (u, \psi_I)_X$, with respect to a wavelet (orthonormal) basis $\{\psi_I\}_{I \in \mathbb{N}}$.

Wavelets in 2D

Each wavelet ψ_I is identified by its scale j, its location $k \in \mathbb{N}_0^2$ and its type $(t) \in \{(v), (h), (d), (f)\}$:

$$\psi_I(x) = \psi_{j,k}^{(t)}(x) = 2^j \psi^{(t)}(2^j x - k).$$

We have:

- If $p = 2^{2J}$ and $J_0 < J$ denotes the coarsest scale, then $j \in \{J_0, \ldots, J_1 = J 1\}$.
- For j ≠ J₀, we have wavelets of the types (v), (h) and (d), whereas for j = J₀ we also have type (f).
- For each level j and type (t), we consider offsets $k = (k_1, k_2), k_1 = 0, \dots, 2^j 1, k_2 = 0, \dots, 2^j 1.$

Iterative Soft-Thresholding Algorithm

Select $w^{(0)} \in \ell_1(\mathbb{N})$ and update:

$$w^{(n)} = S_{\lambda/L} \left(w^{(n-1)} - \frac{1}{L} W R_{\Gamma}^* R_{\Gamma} W^* w^{(n-1)} + \frac{1}{L} W R_{\Gamma}^* m \right),$$

where $S_{\lambda/L}(w)$ is the (component-wise) soft-thresholding operator:

$$[\mathcal{S}_{\lambda/L}(w)]_{I} = S_{\lambda/L}(w_{I}); \qquad S_{\lambda/L}(w_{I}) = \begin{cases} w_{I} + \frac{\lambda}{L} & \text{if } w_{I} < -\frac{\lambda}{L} \\ 0 & \text{if } |w_{I}| \le \frac{\lambda}{L} \\ w_{I} - \frac{\lambda}{L} & \text{if } w_{I} > \frac{\lambda}{L} \end{cases}$$

with L > 0 step size and $\lambda > 0$ regularization parameter.

Once fixed a maximum number of iterations N, the map $m \to W^* w^{(N)} \in X$ is a tentative approximation of the solution map of the inverse problem.

ISTA and Neural Networks

The (unrolled) iterations of ISTA can be considered as layers of a neural network:

$$w^{(n)} = \mathcal{S}_{\lambda/L} \left(w^{(n-1)} - \frac{1}{L} K^{(n)} w^{(n-1)} + \frac{1}{L} b^{(n)} \right),$$

where $K^{(n)} = W R_{\Gamma}^* R_{\Gamma} W^*$ and $b^{(n)} = W R_{\Gamma}^* m$, independently of n, or:

- Main parameters (weight coefficients): $\theta = (K^{(1)}, \dots, K^{(N)}) \in \Theta$;
- Fix the bias vector: $b^{(n)} = WR_{\Gamma}^*m$;
- Other parameters λ , L (which can also be learned), N (hyperparameter).

For a parameter θ , define the map $f_{\theta}: Y \to \ell_1(\mathbb{N})$ associating m to $W^*w^{(n)}$. If $\theta = \theta_0 = (WR_{\Gamma}^*R_{\Gamma}W^*, \dots, WR_{\Gamma}^*R_{\Gamma}W^*)$, f_{θ_0} is equivalent to N ISTA iters.

ISTA as Convolutional Neural Network

Let $\mathbf{K} \in \mathbb{R}^{p \times p}$ represent $R_{\Gamma}^* R_{\Gamma}$ in the wavelet basis. Each block $\mathbf{K}_{j \to j'}^{(t) \to (t')}$ of \mathbf{K} identifies a subband of the wavelet decomposition.

Three key operations to describe the application of each block $\mathbf{K}_{j \to j'}^{(t) \to (t')}$ to the vector $w_i^{(t)}$ of wavelet components:

• Convolution:

$$(C * B)_{k,l} = \sum_{i,j} C_{k-i,l-j} B_{i,j}$$

• Downsampling:

 $\mathscr{D}(B)_{k,l} = B_{2k,2l}$

$$\begin{array}{c|c} b_1 & b_2 \\ \hline b_3 & b_4 \end{array} \longrightarrow \begin{array}{c} b_1 \\ \hline \end{array}$$

• Upsampling:

$$\mathscr{U}(B)[2k:2k+1,2l:2l+1] = \begin{bmatrix} B_{k,l} & 0\\ 0 & 0 \end{bmatrix} \qquad \qquad \boxed{b_1} \longrightarrow \begin{bmatrix} b_1 & 0\\ 0 & 0 \end{bmatrix}$$

ISTA as Convolutional Neural Network

Convolutional representation of $\mathbf{K}_{j
ightarrow j'}^{(t)
ightarrow (t')}$

Let $\delta = |j' - j|$. We have:

$$\int \mathscr{D}^{\delta}(\widetilde{\mathbf{K}}_{j \to j'}^{(t) \to (t')} * W_j^{(t)}) \qquad \quad \text{if} \quad j > j$$

$$\mathbf{K}_{j \to j'}^{(t) \to (t')} w_j^{(t)} = \begin{cases} & \quad \widetilde{\mathbf{K}}_{j \to j'}^{(t) \to (t')} * W_j^{(t)} & \quad \text{if} \quad j = j' \\ & \quad \widetilde{\mathbf{K}}_{j \to j'}^{(t) \to (t')} * \mathscr{U}^{\delta}(W_j^{(t)}) & \quad \text{if} \quad j < j' \end{cases}$$

being $\widetilde{\mathbf{K}}_{j \to j'}^{(t) \to (t')} \in \mathbb{R}^{(2^{\hat{j}+1}-1) \times (2^{\hat{j}+1}-1)}$ (where $\hat{j} = \max(j, j')$):

$$\left[\widetilde{\mathbf{K}}_{j \to j'}^{(t) \to (t')} \right]_d = \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} K(x - x' - 2^{-\hat{j}}d) \ \psi_{j',0}^{(t')}(x') \ \psi_{j,0}^{(t)}(x) dx dx'$$

$$d = (d_1, d_2); \quad d_1, d_2 = \{-2^{\hat{j}} + 1, \dots, 0, \dots, 2^{\hat{j}} - 1\}.$$

Only O(p) elements compared to $p^2 = 2^{4J}$ parameters required to describe the application of $R_{\Gamma}^* R_{\Gamma}$ as a function from \mathbb{R}^p to \mathbb{R}^p .

Tatiana Bubba

Deep neural networks for inverse problems with Ψ DOs: the case of limited angle CT

The element $[W_j^{(t)}]_d = [W_j^{(t)}]_{(d_1,d_2)}$ is the component associated to the basis function $\psi_{j,d}^{(t)}(x) = 2^j \psi^{(t)}(2^j x_1 - d_1, 2^j x_2 - d_2).$

A Working Example – Step 2

Consider the subband $W_4^{(h)}$, namely the case j = 4:

- if j' = 3, then $\delta = 1$ and $\hat{j} = 4$. This means we first compute the convolution between the 31×31 filter $\widetilde{\mathbf{K}}_{4 \to 3}^{(t) \to (t')}$ and the matrix $W_4^{(t)} \in \mathbb{R}^{16 \times 16}$ and then we downsample it to recover the 8×8 matrix describing $\mathbf{K}_{4 \to 3}^{(t) \to (t')} w_4^{(t)}$.
- if j' = 4, then $\delta = 0$ and $\hat{j} = 3$. Hence we compute the convolution of the 31×31 filter $\widetilde{\mathbf{K}}_{4 \to 4}^{(t) \to (t')}$ with the matrix $W_4^{(t)} \in \mathbb{R}^{16 \times 16}$, we get a 16×16 matrix representing the vector $\mathbf{K}_{4 \to 4}^{(t) \to (t')} w_4^{(t)} \in \mathbb{R}^{64}$.
- if j' = 5, then $\delta = 1$ and $\hat{j} = 5$. To compute the 32×32 matrix associated to $\mathbf{K}_{4 \to 5}^{(t) \to (t')} w_4^{(t)}$, we must first upsample the matrix $W_4^{(t)}$ and then convolve it with the 63×63 filter $\widetilde{\mathbf{K}}_{4 \to 5}^{(t) \to (t')}$.

Smaller Filters and How to Get Them

Every layer is an application of $(3(J - J_0) + 1)^2$ convolutional filters and upscaling/downscaling. Is it possible to use smaller filters?

Thresholding strategy

Fix
$$\tau>1$$
 and define $\widetilde{\mathbf{K}}^{\tau}=(\widetilde{\mathbf{K}}_{j
ightarrow j'}^{(t)
ightarrow (t')})_{\tau}$, being $\tau=2\xi+1$, as

$$\begin{bmatrix} \widetilde{\mathbf{K}}^{\tau} \end{bmatrix}_d = \begin{cases} \begin{bmatrix} \widetilde{\mathbf{K}}_{j \to j'}^{(t) \to (t')} \end{bmatrix}_d & \text{ if } \|d\|_{\infty} \leq \tau, \\ 0 & \text{ if } \|d\|_{\infty} > \tau. \end{cases}$$

We can prove that, under suitable assumptions, the above modification is equivalent to a **perturbation of ISTA** (for which convergence can still be proven) and is ensured by the following bound on the elements of the convolutional filters:

$$\left[\widetilde{\mathbf{K}}_{j \rightarrow j'}^{(t) \rightarrow (t')}\right]_d \leq c \frac{2^{-\hat{j}}}{(\|d\|_\infty - 1)^3} \qquad \text{with} \quad \|d\|_\infty > 1.$$

Beyond the Radon Transform

The convolutional representation can be derived for any operator $A: X \to Y$, with X and Y Hilbert spaces, satisfying the following assumptions:

- (strong) sparsity: $w^{\dagger} \in \ell^{0}(\mathbb{N});$
- $A: X \to Y$ is injective;
- A is a convolutional kernel operator:

$$(A^*A\psi_I, \psi_{I'})_X = \int_{\mathbb{R}^2} \int_{\mathbb{R}^2} K(x, x')\psi_I(x)\psi_{I'}(x')dxdx';$$

with K(x,x') = K(x-x'). Moreover, the kernel K is smooth away from the diagonal and satisfies (Calderón-Zygmund kernel)

$$K(x, x') \le \frac{C}{|x - x'|}, \quad |\nabla_x K(x, x')| + |\nabla_{x'} K(x, x')| \le \frac{C}{|x - x'|^2};$$

• first-order vanishing moment: each wavelet basis function ψ_I satisfies

$$\int_{\mathbb{R}^2} \psi_I(x) dx = 0.$$

PDONet: a Network to Learn Pseudodifferential Operators

We define the Convolutional Neural Network $f_{\theta}^{\tau}: Y \to X$, called ΨDONet :

$$w^{(n)} = S_{\frac{\lambda}{L}} \left(w^{(n-1)} - \frac{1}{L} K^{(n)} w^{(n-1)} + \frac{1}{L} W A^* m \right),$$

where $K^{(n)}$ corresponds to the block-wise convolution operator (combination of \mathscr{U} , \mathscr{D} and convolution) and $\theta = (K^{(1)}, \ldots, K^{(N)})$, possibly collecting other learnable parameters (λ, L) and hyperparameters (N, τ) .

 Ψ DONet can do better than ISTA:

- reduce numerical errors induced by the discrete representation of A^*A ;
- mitigate model errors in the definition of the operator A itself;
- might provide a representation of A^*A with respect to a slightly different basis, which better fulfils the sparsity assumption on the solutions.

T.A. Bubba, M. Galinier, M. Lassas, M. Prato, L. Ratti and S. Siltanen, *Deep neural networks* for inverse problems with pseudodifferential operators: an application to limited-angle tomography, submitted, arXiv:2006.01620, 2020.

ΨDONet and Fourier Integral Operators

In each layer, the network f_{θ}^{τ} applies the filters associated to an operator whose kernel is $K_0 + K_1$, where K_0 is the kernel of A^*A and K_1 is the kernel of another learned operator.

It works also for FIOs like R_{Γ} : largest entries of the convolutional filters representing $R_{\Gamma}^* R_{\Gamma}$ are located in the center and along some lines, stretching away from the center (bowtie filters).

Ψ DONet: a Convergence Result

Optimal network convergence

Let

$$\mathcal{L}(\theta;\mu,\nu) = \mathbb{E}_{u \sim \mu, \epsilon \sim \nu} \left[\left\| f_{\theta}^{\tau}(A_{p,q}u + \epsilon) - Wu \right\|_{\ell^{2}}^{2} \right]$$

be the loss function associated to the network f_{θ}^{τ} . As δ converges to 0, there exists a constant c^* , depending on $C_{\mathcal{B}}$ and τ , such that

$$\mathcal{L}(\theta^*; \mu, \nu) \le c^* \delta^2.$$

where:

- $A_{p,q}$ is a representation of A in the subspaces $X_p = \operatorname{span}\{\psi_I\}_{I=1}^p$ and $Y_q = \operatorname{span}\{\varphi_j\}_{j=1}^q$;
- X_p is restricted to $\mathcal{B} = \{u \in X_p : Wu \in \ell^1(\mathbb{N}); ||Wu||_{\ell^1} \leq C_{\mathcal{B}}\}$, with probability density μ (prior knowledge on the exact solution);
- *ϵ* is a Gaussian random vector with probability density ν (prior knowledge on the noise), *i.e.*, ν = N(0, σ²I_q);
- θ^* : minimizer of the loss function $\mathcal{L}(\theta; \mu, \nu)$ associated to f_{θ}^{τ} .

In Practice: Discretization and Implementation

For $\mathbf{u}^{\dagger} \in \mathbb{R}^{p}$ we obtain the linear model

$$\mathbf{m} = \mathbf{R}_{\Gamma} \mathbf{u}^{\dagger} + \epsilon, \tag{1}$$

where $\mathbf{R}_{\Gamma} \in \mathbb{R}^{q \times p}$ (discretized line integrals) and $\epsilon \in \mathbb{R}^{q}$ (noise).

The regularized minimization problem reads as:

$$\min_{\mathbf{w}\in\mathbb{R}^p} \|\mathbf{R}_{\mathbf{\Gamma}}\mathbf{W}^*\mathbf{w} - \mathbf{m}\|_2^2 + \lambda \|\mathbf{w}\|_1$$

where $\mathbf{W} \in \mathbb{R}^{p imes p}$ represents a discretization of the wavelet transform and

 $\mathbf{W}\mathbf{u}^{\dagger}=\mathbf{w}^{\dagger}\in\mathbb{R}^{p}.$

Ψ **DONet in Practice**

Convolutional implementation of ISTA:

$$\mathbf{w}^{(n+1)} = S_{\frac{\lambda}{L}} \left(\mathbf{w}^{(n)} + \frac{1}{L} \left(\mathbf{W} \mathbf{R}_{\Gamma}^* \mathbf{m} - \mathbf{K} \mathbf{w}^{(n)} \right) \right), \qquad n = \{0, \dots, N\}$$

where $S_{\lambda/L}$ is the (component-wise) soft-thresholding operator.

 ${\bf K}$ is converted into a partially trainable CNN:

- only the center of the convolutional filters is learned (τ -thresholding);
- also the regularization parameter λ and the step size L are learned.

TA as CNN 00000000 ⊈DONet 0000000000000 Results 000 Conclusions

Ψ DONet-F: Filter-Based Ψ DONet

The model for Ψ **DONet-F** reads as:

$$\mathbf{w}^{(n+1)} = \mathcal{S}_{\gamma_n} \left(\mathbf{w}^{(n)} + \alpha_n \left(\mathbf{W} \mathbf{R}^*_{\mathbf{\Gamma}} \mathbf{m} - \beta_n \left(\breve{\mathbf{K}}^{\tau} \mathbf{w}^{(n)} + \Lambda^{\tau}_{\zeta_n} \mathbf{w}^{(n)} \right) \right) \right)$$

where Λ_{ζ_n} denotes a single-layer of the CNN with $n = \{0, \ldots, N\}$, the parameters to be learned are $\{\gamma_0, \alpha_0, \beta_0, \zeta_0, \ldots, \gamma_N, \alpha_N, \beta_N, \zeta_N\}$.

Clear interpretation: modifying the weights of ${\bf K}$ through the learning process can be thought of as a direct improvement of the back-projection operator

0000	000	00000000	000000000	000	000

Ψ DONet-O: Operator-Based Ψ DONet

The model for Ψ **DONet-O** reads as:

$$\mathbf{w}^{(n+1)} = \mathcal{S}_{\gamma_n} \left(\mathbf{w}^{(n)} + \alpha_n \left(\mathbf{W} \mathbf{R}_{\Gamma}^* \mathbf{m} - \mathbf{W} \mathbf{R}_{\Gamma}^* \mathbf{R}_{\Gamma} \mathbf{W}^* \mathbf{w}^{(n)} \right) + \beta_n \Lambda_{\zeta_n}^{\tau} \mathbf{w}^{(n)} \right)$$

where $n = \{0, \ldots, N\}$, the parameters to be learned are $\{\gamma_0, \alpha_0, \beta_0, \zeta_0, \ldots, \gamma_N, \alpha_N, \beta_N, \zeta_N\}$ and Λ_{ζ_n} has the same architecture as the operator **K**.

Clear interpretation: it can still be seen as an adjunct for improving the back-projection operator and it offers an implementation numerically preferable to Ψ DONet-F.

About the Soft-thresholding Parameters

From a theoretical point of view, the soft-thresholding parameters $\gamma_0, \ldots, \gamma_N$ in Ψ DONet-F and Ψ DONet-O have to be **non-negative**.

Two options:

- Stick to standard ISTA: enforce positivity by replacing each γ_n by $10^{\tilde{\gamma}_n}$, where $\tilde{\gamma}_n$ becomes the actual trainable parameter.
- Allow for a greater degree of freedom in the learning process, no longer soft-thresholding: S_{γn<0} is defined as the symmetric of the soft-thresholding curve with respect to y = x.

$$\mathcal{S}_{\gamma_n}(x) = \begin{cases} \operatorname{For} \gamma_n \ge 0 : & \operatorname{For} \gamma_n < 0 : \\ x - \gamma_n, & \operatorname{if} x \ge \gamma_n \\ 0, & \operatorname{if} |x| < \gamma_n \\ x + \gamma_n, & \operatorname{if} x \le -\gamma_n \end{cases} \qquad \qquad \qquad \mathcal{S}_{\gamma_n}(x) = \begin{cases} x - \gamma_n, & \operatorname{if} x \ge 0 \\ x + \gamma_n, & \operatorname{if} x < 0 \end{cases}$$

00000	000	000000000	0000000000	•00	000
		Setup			

• Data set:

- 10700 synthetic images of ellipses, sized 128×128 , with number, locations, sizes and intensity gradients chosen randomly
- $\bullet~10000$ images for training, 200 validation and 500 for testing
- missing wedge of 60°

• Operators:

- \mathbf{R}_{Γ} : Matlab's radon for simulating data; parallel beam geometry function of ODL (based on Astra toolbox) in Ψ DONet
- W: Python's pywt with J = 7 and $J_0 = 3$ (*i.e.*, 10 subbands)

• Network and training:

- Tensorflow with Adam optimizer
- 40 different sets of trainable parameters: $\{\zeta_n, \gamma_n, \alpha_n, \beta_n\}$ used over 3 consecutive blocks
- N = 120, $\tau = 32$; learning rate: 10^{-3} ; epochs: 3; batch size: 25.

Conclusions

- limited angle CT is a special inverse problem
 - Ψ **DOs** and **FIOs** theory
- ISTA, wavelets and unrolled neural networks
 - ISTA can be interpreted as a Convolutional Neural Network
 - convergence results on ISTA imply the convergence of the CNN solution

• Ψ **DONet** for learning Ψ DOs and FIOs

- split the convolutional kernel $K = K_0 + K_1$: fix K_0 , learn K_1
- convolution, upsampling and downsampling *exactly* prescribed thanks to the "convolutional representation"
- two equivalent implementations: Ψ DONet-F and Ψ DONet-O
- data-driven inversion: limit influence of DL
 - combine knowledge from traditional inverse problems theory with data-driven techniques
 - clearer idea of what is happening!

Limited Angle Tomography	IP and Sparsity	ISTA as CNN	⊉DON et	Results	Conclusions			
	000	000000000	0000000000	000	O●O			
Eutoma Durana ata								

Future Prospects

• Generalization problem: convergence of the trained network

- Moving towards real data:
 - bigger images (now training on 512×512)
 - smaller visible wedges (e.g., in breast CT $\phi = 20^{\circ}$ with 11 sampled angles)
 - loss function: structural similarity metric (SSIM) in the wavelet domain
 - loss function: additional regularization
 - work on hyperparameter optimization
- Extension to other inverse problems with Ψ DOs and FIOs:
 - geodesic X-ray transform (applications in seismic imaging)
 - synthetic-aperture radar (SAR)

Thank you!
